

Impact of AI Adoption on Workforce Attrition - End to End Project

Business Problem Statement

As organizations accelerate the adoption of artificial intelligence tools across workflows, early gains in efficiency are often prioritized over long-term workforce impact.

However, there is increasing concern that higher reliance on AI may be introducing unintended negative consequences for employees.

Rising levels of burnout, growing fear of job displacement, and increasing attrition risk are emerging as potential side effects of AI-driven work environments. At the same time, companies are progressing through different stages of AI maturity, without clear visibility into how these transitions are affecting employee wellbeing and retention.

Without a structured analysis, organizations risk optimizing for short-term productivity while overlooking deeper workforce instability.

Your Task

As a Data Analyst, you should evaluate the **hidden costs of AI adoption** by examining how AI usage intensity, tool dependency, and organizational AI maturity influence:

- Employee burnout
- Perceived job security
- Job satisfaction
- Attrition risk

The goal is to identify patterns that signal **workforce strain, over-reliance on AI, potential retention issues and attrition risk**, enabling organizations to take proactive steps before these risks escalate.

This project should analyze whether rapid AI adoption is quietly increasing burnout, job insecurity, and attrition risk across the workforce.
